

In vitro fertilization (IVF)

In vitro fertilization (IVF) is a complex series of procedures used to help with fertility or prevent genetic problems and assist with the conception of a child. During IVF, mature eggs are collected (retrieved) from ovaries and fertilized by sperm in a lab. Then the fertilized egg (embryo) or eggs (embryos) are transferred to a uterus. One full cycle of IVF takes about three weeks. Sometimes these steps are split into different parts and the process can take longer. IVF is the most effective form of assisted reproductive technology. The procedure can be done using your eggs and your partner's sperm. Or IVF may involve eggs, sperm or embryos from a known or anonymous donor. In some cases, a gestational carrier – a woman who has an embryo implanted in her uterus – might be used. Your chances of having a healthy baby using IVF depend on many factors, such as your age and the cause of infertility. In addition, IVF can be time-consuming, expensive and invasive. If more than one embryo is transferred to your uterus, IVF can result in a pregnancy with more than one fetus (multiple pregnancy). Your doctor can help you understand how IVF works, the potential risks and whether this method of treating infertility is right for you.
